Abstract

Carex kotagirica, a new species of Cyperaceae is described from southern India. It differs from the closely allied C. ligulata and C. pseudoligulata by the shorter habit and in a combination of floral characters.

Keywords: Carex, new species, Nilgiri, southern India

Introduction

Carex L. is one of the largest genera of flowering plants and the largest in the family Cyperaceae. According to Goetghebeur (1998) there are about 2000 species in the world. Mabberley (2008) reported c. 1800 species under this genus, and as per the World Checklist (WCSP, 2015) it comprises 1816 species. In India, too, Carex is the largest genus of family Cyperaceae and according to Sharma (2000) it is the second largest genus of vascular plant families. Karthikeyan et al. (1989) reported of 160 species, one subspecies and 29 varieties which includes a few from the neighbouring countries. However, including the new reports in the recent past, at present the total number of species in the country is estimated to be c.160.

The genus is characterised by the presence of bottle-shaped utricles, which are homologous with the prophylls enclosing the female flower or achene. Carex of Asia was divided in different ways by different workers. Clarke (1894) treated all the distigmatic species under the subgenus Vignea and the tristigmatic species under the subgenus Eu carex. Koyama (1962) divided it into two subgenera as Vignea and Carex (Eucarex). Kern and Nooteboom (1979) followed almost same classification by treating the distigmatic species with lenticular achenes as subgenus Vignea and the tristigmatic ones with trigonous achenes as subgenus Carex. But certain distigmatic species that have peduncled spikes or a terminal male spike were also treated under subgenus Carex. In recent Floras the genus is divided into the subgenera Psyllophora, Vignestra, Vignea and Carex by Kukkonen (2001) and into Vignea, Vignestra and Carex by Lunkai et al. (2010).

During a recent fieldwork in the forests of Nilgiri hills in southern India, specimens of an interesting species of Carex were collected. A detailed study of the specimens and a perusal of the literature revealed that it is a new species allied to C. ligulata and C. pseudoligulata. The former is widely distributed in Indian subcontinent and China to Japan through Thailand, and the latter is endemic to China. The new taxon differs from these two mainly by its shorter habit and a combination of floral characters. The main differences are shown in Table 1.

The new species described here can be placed under subgenus Carex, section Propriae, characterized by a terminal male spike. A detailed description of the plant is provided along with an illustration and Scanning Electron Microscope (SEM) images of the utricle and achene.

Carex kotagirica can be distinguished from the closely allied C. ligulata by its smaller habit, short leaves, and short spikelets, utricles and achenes. It can also be differentiated from C. pseudoligulata by its smaller habit, short spikelets, and larger female glumes and utricles. Also utricles are densely hirsute in C. kotagirica. But in C. pseudoligulata utricles are hispidulous on the veins and upper margins only.

Carex kotagirica A. Maji & V.P. Prasad sp. nov.

**Type:** INDIA: Tamil Nadu, Nilgiri dist., Way to Kotagiri, 02.09.2014, V.P. Prasad & Animesh Maji 58467 (holotype CAL!, isotypes CAL!, MH!).

Perennial with short rhizome, 20–25 cm high. Rhizome ultimately woody, clothed with blackish remnants of old bladeless sheaths; roots wiry. Culms densely tufted, erect, trigonous, 3–4 mm thick, 5–7-noded, enclosed by the leaf sheaths; internodes 2.5–3 cm long, pubescent on the angles. Leaves 5–7 per culm, linear-lanceolate, acuminate at apex, 12–17 cm long, 5–7 mm wide, scabrous on the margins towards apex; lowest ones reduced to bladeless sheath or with a short lamina; sheaths hairy on the angles towards the mouth, membranous on the margin towards the lamina. Inflorescence with 3–5 somewhat closely arranged spikes. Bracts foliaceous, sheathing, exceeding the inflorescence. Spikes unisexual, peduncled, the terminal one male and all others females. Male spike erect, terete, on c. 1 cm long peduncle, linear, 7–10 × 1.5–2 mm, brownish, many-flowered. Male glumes membranous, oblong-ovate, acute to obtuse at apex, minutely to prominently mucronate, rarely some of the glumes muticous, 3–3.5 × 1.5–2 mm, with a prominent midrib which often surpass into a ciliate micro, brown dotted along the mid-vein and on both sides in upper half, pubescent along the upper margins. Stamens 3; filaments elongate up to 3 mm; anthers linear-oblong, c. 1.3 mm long. Female spikes erect to somewhat spreading, on a 4–6 mm long peduncle, cylindrical, oblong, 12–20 × 5–7 mm, densely many-flowered (8–20). Female glumes oblong-ovate, acute or at times somewhat retuse at apex, mucronate, 3–3.3 × c. 2 mm (including the micro), with a prominent mid-vein extending to up to 0.3 mm long micro, stramineous when dry, with brown dotted along the mid-vein and on both sides in the upper half, pubescent along the upper margins. Style c. 1.5 mm long; stigmas 3, protruding through the apex of the utricle. Utricle trigonous, ellipsoid, 4–4.5 × 1.2–1.7 mm (including the 1.1–1.5 mm long beak), brownish, densely hirsute, beaked; beak bifurcate at apex. Achene trigonous, ellipsoid, 1.8–2.2 × c. 1.1 mm, brownish.

**Flowering & Fruiting:** August – September.

**Distribution:** Endemic to the Nilgiris, Tamil Nadu, India. Found in moist forests on the hills, c 1800 m.

**Conservation status:** Data Deficient (DD) as per the IUCN categories (2001). The available information is inadequate to assess the risk factor, though the plant was found in a single locality. Therefore, more field work is required to determine the exact range of distribution and its population.

Acknowledgements

The authors are grateful to the Director, Botanical Survey of India, Kolkata and the Head of Office, CAL for the facilities. Grateful thanks are to Dr. David Simpson, Royal Botanic Gardens, Kew, UK for his comments and opinion on the new species. Thanks are due to the Divisional Forest Officers, Nilgiris, Tamil Nadu for the assistance in field work. Thanks are also due to Mr. D. K. Sah, Artist, Botanical Survey of India, Kolkata for preparing the illustration.
